K-Wing specializes in Stainless steel grade 304 and 316 hardware manufacturing. Production include precision casting, hot forging and machining. Product include special OEM manufacturing for Architecture, such as handrail fitting, turnbuckles, glass fitting and wire terminals. Marine hardware productions such as stainless snap shackles, wire terminals, anchors, cleat and special designed marine fitting.

Our stainless steel production focuses on four principal processes. Although a variety of additional finishing processes may be used on the end product, the main forming methods of stainless steel remain: Casting, Forging, Press forming, and Machining.

Principal Stainless Steel Forming Methods:

1) Casting

Casting (or lost wax casting) as its name implies, utilizes the free shape forming of wax followed by 5 layers of ceramic shell made of silicon mallet sand. Each layer of ceramic shell applied is of a different grade; they must cover thoroughly and be dry before the next layer is added on the top of the previous layer. When all five layers of ceramic are formed securely, the wax inside the using steam, heat and pressure. Molten stainless steel is then poured into the ceramic moldings for the product to take shape.

ceramic is removed

2) Forging

Forging utilizes mainly round bar sections, heated to 1020C forging temperature. At this temperature, the stainless is soft enough for press forming, but does not melt. Using high compression and dies, the required form of the product can be produced. The Advantages of Forging components is its strength. The molecules are highly compacted to form very high-strength components. The disadvantages of Forging components are the limited forms and shapes as well as high molding costs.

3.) Press Forming

Press forming refers to using processed sheets to compression "cut" by means of a Press. This form of manufacturing can be very economical as form sheets can be bent into any desired shape. However the disadvantages are the limited thickness as well as high molding cost. A variety of after-forming processes, including welding and assembly, can be added to Press forming products to achieve the desired end product.

4) Machining

Machining consist of taking a solid block of Stainless steel, or a round bar section, and by means of cutting/ carving, called Turning and Milling, the desired object is achieved. Just about any shape or form can be achieved by the combination of these two processes. Never-the-less these are not ideal manufacturing procedures and depending on the form required, it may take several hours just to achieve one single item. However, in some cases and depending on the shape of the required product, machining may be the most economical and fastest production method. Also, due to the fact that machining is always done from a wrought-worked block of stainless steel or a solid round bar, the strength on the final product may be as high as that of forged products.

To overcome the constraints of one single forming method, a production design with a combination of production methods is the best solution. Please notify us in advance whenever possible when you need assistance in designing your desired product. This will reduce tool costs as well as time in production.

Finish Details:

1) Threading

Threading can be classified in general as internal threading or external threading.

In internal threading, threads are on the inside of a circular tube and this process is referred to as Tapping. Tapping is usually preceded by drilling to achieve the specified dimensions before the internal threads are tapped.

External threads may be produced by Rolling or Cutting. In rolling, the bar is pre-finished to specified dimensions, and using compression of two roller dies the thread is pressed into form. These threads are easy to press and are on average 25% stronger than a Cut thread. However, Roller threads require more expensive equipment and more product. Cut threads are on the other hand produced by a simple turning machine. The cost of production per unit may be high, but it is the most economical method when quantities of required pieces are small or very odd-thread specifications are required.

2) Welding

Welding stainless steel is more critical than normal steel welding. In order to protect contaminating the exposed surface of heated stainless steel, a protective layer of Argon is applied. Further Fillers may be added to extend the strength of the desired products. The two most common welding processes are TIG and MIG welding. MIG uses a higher temperature and thus results in a stronger and more expensive weld.

3) Surface Finish

Surface finish is one of the most critical areas of product design; it will determine how end users perceive the value of the product as well as product resistance to the environment and tea stain. Deciding on a product's finished surface is best achieved by considering the environment where the item will be used. As a general rule of thumb, the finer the surface, the more the cost of manufacturing as well as better Corrosion resistance.

- a.) **Mirror polished finish** is the most expensive of all finishes. It involves several layers of fine grinding and waxing to arrive at a mirror exterior. Due to the fine finish it is least

susceptible to tea stain forming. For this reason marine fittings, which are exposed to sea water, are finished this way.

Machine finish is turned (cut) on a Lathe. This results in a very uniform, lined finish and thus has a very mechanical look to it. Matt finish is polished by a satin grade of 800 rollers; it provides a non-reflective surface similar to Machined finish.

Sand blasting finish uses a combination of blast elements; most popular are glass beads to uniformly destroy the surface; light is then reflected from within the spherically dented surface created by the blasting. This surface is very popular for interior designers for its aesthetic affect as well as its finger-print-resistant feature.

d.) Electro polished finish uses electricity in a tank of chemicals. Similar to a wet battery setup, the outer layer of molecules of the stainless steel product is peeled away exposing the Chromium molecules resulting in a shining and corrosion-resistance finish.

4) Passivation

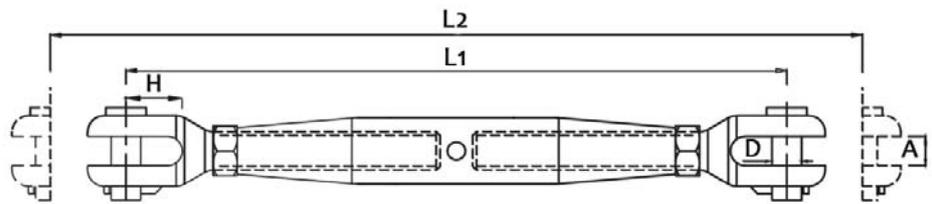

Passivation is the process of making a material "passive" in relation to other contaminants. In stainless steel this is achieved by rinsing the items with a dilute solution of nitric acid and peroxide alternating with deionized water. The nitric acid and peroxide oxidizes and dissolves any impurities on the exposed surface of the stainless fitting, and the deionized water rinses away the acid and oxidized impurities. This process adds an extra layer of protection to Stainless steels surfaces.

Once a stainless steel product goes through the above main forming methods, a variety of finishing details will follow. In this section we will cover the most common methods of stainless steel finishing processes.

Requesting a quotation is simple: send us a physical sample or electronic drawing in .dwg / pdf file of the product you are after together with the following information:

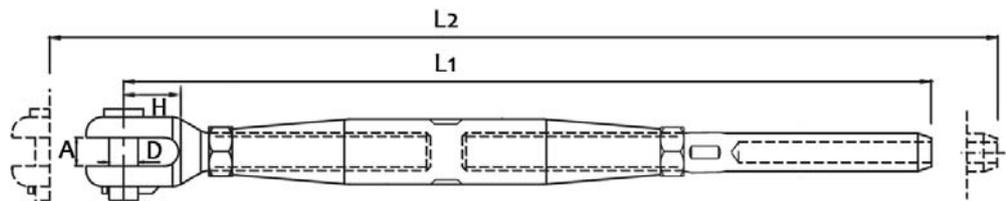

- a.) Quantity**
- b.) Name of material**
- c.) Method of manufacturing**
- d.) Grade or UNS number**
- e.) Tolerances**
- f.) Heat treatment**
- g.) End finish required**
- h.) Surface conditions**
- i.) Test report required**
- j.) Packaging methods**
- k.) Shipment methods**

Should you not have the above information, we will work with you to determine a best value format to suit your needs. The more detailed information we receive in regard to the use of the item will allow us to better suggest production methods to maximize value and reduce production time.
